Beta-nucleating, light stabilizing agents for polypropylene

The present invention relates to a composition containing a crystalline polypropylene resin and one or more sterically hindered amine derivatives capable of acting as light stabilizers and nucleating agents for the formation of the β -crystal form, to the use of these derivatives as light stabilizing, β -nucleating agents and to articles made from a polypropylene resin containing the β -form crystals.

It is known that crystalline polypropylene may occur in α , β , γ and δ crystal forms as well as in the smectic crystal form which is formed on quenching of melted polypropylene. The β -crystal form (hereinafter referred to as " β -form") differs from the more common α -form which is found, for instance, in the conventional natural pellets in that it is lower in melting point and in density, not to speak of differences in the mode of crystallization and of fracture, thus being of interest from application points of view (Kobunshi Kagaku 30, 694 - 698, (1973)).

The β -form of polypropylene is less stable compared with the corresponding α -form under usual processing conditions. When melts of polypropylene are extruded and then cooled the α -form of polypropylene tends to predominate. However, polypropylene containing high contents of the β -form can be prepared by the addition of a suitable nucleating agent which induces the formation of the β -form when the polypropylene is molten and subsequently cooled.

US-B-6,235,823 describes for example the use of diamide compounds as β -nucleating agents. Not any nucleating agent for polypropylene resins does necessarily induce the formation of the β -crystal form.

The present invention relates in particular to a light stabilized composition containing

- (1) a crystalline polypropylene resin and

The amount of the β -nucleating, light stabilizing agent (component (2)) to be added to the polypropylene resin is not critical insofar as the desired effect can be obtained. Generally, it is used in an amount effective for increasing the content of the β -crystal form. 0.0001 to 5 %, in particular 0.001 to 2 %, 0.05 to 1 %, 0.1 to 1 % or 0.15 to 1 %, relative to the weight of component (1), are suitable.

Thus, the β -nucleating, light stabilizing agent of the invention is capable of causing a crystalline polypropylene resin to undergo transition to the β -crystal form at a very low level of

addition and a molded product having a β -form crystal content as indicated above can be obtained under suitable molding conditions.

Component (3) is preferably present in the composition according to the present invention in an amount of 1 to 90 %, for example 2 to 80 % or 5 to 50 %, relative to the weight of component (1).

A further embodiment of the present invention is a method for improving the light stability of a polypropylene resin and for providing said polypropylene resin with a content of β -form crystals of at least 5 % calculated by means of the following equation

$$\beta\text{-form crystal content (\%)} = 100 \times P_{\beta 1} / (P_{\alpha 1} + P_{\alpha 2} + P_{\alpha 3} + P_{\beta 1})$$

where $P_{\alpha 1}$ to $P_{\alpha 3}$ are respective peak heights (maxima) of the α -form and $P_{\beta 1}$ is a peak height (maximum) of the β -form determined by wide angle X-ray scattering, which comprises incorporating into the polypropylene resin one or more β -nucleating, light stabilizing agents of the formula (I).

Another embodiment of the present invention is the use of a compound of the formula (I) as β -nucleating agent for a polypropylene resin.

The resin compositions of the present invention may be prepared by standard procedures, well known to those skilled in the art, of compounding, such as mixing the prescribed components in a conventional mixer by e.g. dry-blending or solution spraying and melting and kneading the mixture with a single- or twin-screw extruder, or the like.

The β -nucleating, light stabilizing agent of the formula (I) can be added to the polypropylene resin at an optional stage, i.e. either during the polymerization reaction or after the polymer has been prepared.

To the resin compositions of the present invention, additional materials can be added in a concentration range that does not adversely affect the beneficial effects of the invention. These

materials may include stabilizers, antioxidants, antibacterial agents, ultraviolet absorbers, thermostabilizers, light stabilizers, neutralizers, antistatic agents, antiblocking agents, heavy metal inactivation agents, flame retardants, lubricants, peroxides, hydrotalcite, foaming agents, elastomers, processing aids, additional nucleating agents, reinforcing matter, plasticizer and the like and mixtures thereof.

In general, the conventional additive is present in the composition of this invention in an amount of preferably 0.0001 to 5 % or 0.001 to 3 %, in particular 0.01 to 2 % or 0.01 to 0.25 %, relative to the weight of component (1).

The polypropylene resin of component (1) preferably contains one or more process stabilizers, e.g. in an amount of 0.001 to 2 %, relative to the weight of component (1).

Examples of processing of the resin compositions according to the present invention are: Injection blow molding, extrusion, blow molding, rotomolding, in mold decoration (back injection), slush molding, injection molding, co-injection molding, forming, compression molding, pressing, film extrusion (cast film; blown film), fiber spinning (woven, non-woven), drawing (uniaxial, biaxial), annealing, deep drawing, calendering, mechanical transformation,

sintering, coextrusion, coating, lamination, crosslinking (radiation, peroxide, silane), vapor deposition, weld together, glue, vulkanization, thermoforming, pipe extrusion, profile extrusion, sheet extrusion; sheet casting, spin coating, strapping, foaming, recycling / rework, extrusion coating, visbreaking (peroxide, thermal), fiber melt blown, spun bonded, surface treatment (corona discharge, flame, plasma), sterilization (by gamma rays, electron beams), gel-coating, tape extrusion, SMC-process or plastisol.

The resulting crystalline polypropylene resin composition of the present invention are preferably molded by injection, compression, blow molding, roto molding and / or other known molding techniques utilizing the conventional molding machines. Molding conditions may be those commonly employed. Typical preferred molding conditions may be as follows. Injection molding: resin temperature about 180 to 320°C, preferably about 200 to 300°C; mold temperature about 0 to 120°C, preferably about 30 to 80°C. Blow molding: resin temperature about 180 to 300°C, preferably about 200 to 280°C; mold temperature about 20 to 140°C, preferably about 60 to 120°C. Compression molding: temperature of melted resin about 180 to 300°C, preferably about 200 to 280°C; cooling temperature about 10 to 125°C, preferably about 30 to 100°C.

Molded products, which contain much higher proportion of β -crystal form than the reference material and which are satisfactory in the aspect of color, can be easily obtained by molding under the above-mentioned molding condition the resin composition of the invention prepared with use of, for instance, the above-mentioned mixing method. Compared with the conventional polypropylene pellet which normally does not substantially contain β -crystals but is predominantly composed of α -crystals, the polypropylene molded product has a lower melting point and requires a lower force for deformation under heating. Therefore, the molded products contribute a great deal to improved secondary processability and mechanical characteristics. The products encompass a wide variety of forms such as packaging, containers, bumpers, housing, technical article (e.g. gear) and so on.

With the resin compositions of the present invention, the ratio of α - to β -form in the final product can be controlled as desired by suitable solidification conditions. It is possible to control the ratio of α - to β -form by appropriately selecting cooling conditions under the above molding condition. This characteristic is beneficial particularly in the surface roughening of,

for instance, biaxially oriented films and fibres. The film having such a roughened surface displays excellent antiblocking property, printability and adhesion, etc. and is of great use in the fields of packaging film, printing paper, tracing paper, oil-immersion type plastic capacitors and so on.

A 2.5 l three neck flask equipped with a stirrer, thermometer and condenser is charged with 153.3 g (1.0 mol) of 4-amino-2,2,6,6-tetramethylpiperidine, 12.5 g (0.29 mol) of dry lithium chloride, 223 g (2.16 mol) of triethylamine and 750 ml of N-methylpyrrolidone (NMP). The mixture is cooled to 5 °C and a solution of 76.9 g (0.375 mol) of terephthaloyl chloride in 250 ml of NMP is added within 30 minutes. The yellow suspension is then heated to 75 – 80 °C and stirred for 2 hours. After cooling the reaction mixture is poured in 3 l of ice water. The precipitate is recovered by filtration and dried under reduced pressure at 100 °C. The obtained raw product is then recrystallized from 1l of NMP. The desired product is obtained in form of white crystals.

The reaction product is then diluted with 200 ml of isopropanol/water (1/4). The reaction mixture is then poured on 600 ml of water, under stirring. Then, the solid residue is filtered off and subsequently washed with several portions of isopropanol/water (1/1). Afterwards, the solid is dried in a vacuum drier at 80°C for 15 hours. The desired product is obtained as a colourless powder.

In the examples below, the following procedures are applied.

Determination of the β -form crystal content by wide angle X-ray scattering (WAXS):

A Siemens (RTM) wide angle X-ray diffractometer (Model D500) is used for the analysis of the β -modification content of the specimen prepared as described below. The test specimen is placed in a sample holder in the middle between the copper K_{α} radiation source ($\lambda = 1.54178 \text{ \AA}$) and the detector. The sample is rotated during the recording at 2 rpm. The diffraction pattern is recorded from $2\Theta = 5 - 35^{\circ}$ at an increment of 0.025° and a recording time of 1 sec. The β -form crystal content is determined as described by A. Turner Jones et al., Makromol. Chem. 75, 134 (1964) and in US-A-5,491,188 according to the following equation:

$$\beta\text{-form crystal content (\%)} = 100 \times P_{\beta 1} / (P_{\alpha 1} + P_{\alpha 2} + P_{\alpha 3} + P_{\beta 1})$$

where $P_{\alpha 1}$ to $P_{\alpha 3}$ means the maximum peak heights of the α -form and $P_{\beta 1}$ means the maximum peak height of the β -form determined by wide angle X-ray scattering.

$P_{\beta 1}$ is a reflection intensity (height) on (300) plane of β -form crystal.

$P_{\alpha 1}$ is a reflection intensity (height) on (110) plane of α -form crystal.

$P_{\alpha 2}$ is a reflection intensity (height) on (040) plane of α -form crystal.

$P_{\alpha 3}$ is a reflection intensity (height) on (130) plane of α -form crystal.

Differential Scanning Calorimetry (DSC):

A Perkin-Elmer DSC instrument (RTM) (Model DSC 7), operated in a dry nitrogen atmosphere, is used for the analysis of the crystallization behavior of the various samples, according to standard procedures. About 5 to 10 mg of sample is sealed into an aluminum cup, heated from 130°C to 230°C at a rate of $10^{\circ}\text{C}/\text{min}$, held at 230°C for 5 min, and then subsequently cooled at a rate of $10^{\circ}\text{C}/\text{min}$ to 50°C . The data represented as crystallization temperatures are the peak temperatures of the exotherms (predominant peak minimum) in the thermograms that are recorded upon cooling.

Example I:

2.5 kg of polypropylene powder (Moplen FL F 20 (RTM) of Montell (RTM)) are mixed to homogeneity in a high-speed mixer with 0.10 % of tris(2,4-di-tert-butylphenyl)phosphite, 0.05 % of pentaerythritol tetrakis 3-(3,5-di-tert-butyl-4-hydroxyphenyl)propionate, 0.10 % of calcium stearate and 0.20% of Compound A. This blend is then extruded in a twin-screw extruder of Berstorff (RTM) at a temperature of at most 240°C. After drawing the extrudate through a waterbath to cool, it is granulated.

55g of the granules are molten at $T_1=240^{\circ}\text{C}$ for 15 min in a melt press Suter LP 322 (RTM). Subsequently, the molten polypropylene resin composition is put in a second melt press (Suter LP 322 (RTM)) which has a temperature of $T_2=110^{\circ}\text{C}$. The samples are pressed at $p=10$ bar and are annealed / crystallized for 60 min at the indicated temperature T_s . The β -form crystal content is shown in Table 1.
